Webinar

Blast Time History Analysis in RFEM

Questions During the Presentation

GoToWebinar Control Panel
Desktop

The screenshot shows the GoToWebinar control panel interface. Three blue callout boxes with arrows point to specific features:

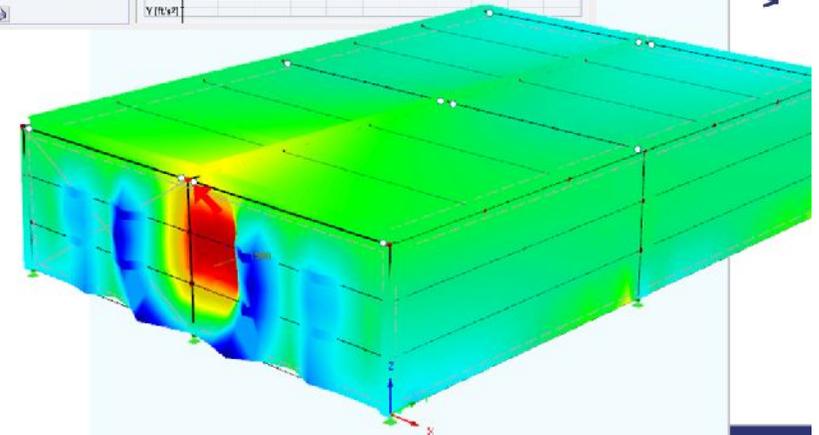

- Show or hide control panel:** Points to the left-hand sidebar containing icons for audio, chat, and other controls.
- Adjust audio settings:** Points to the 'Audio' section, which includes a 'Sound Check' indicator, radio buttons for 'Computer audio' (selected) and 'Phone call', a 'MUTED' status, and dropdown menus for 'Mikrofon (2- Sennheiser USB h...)' and 'Lautsprecher (2- Sennheiser U...)'.
- Ask questions:** Points to the 'Questions' section, which features a text input field with the placeholder '[Enter a question for staff]' and a 'Send' button.

At the bottom of the control panel, the 'Webinar ID: 373-901-987' and the 'GoToWebinar' logo are visible.

Content

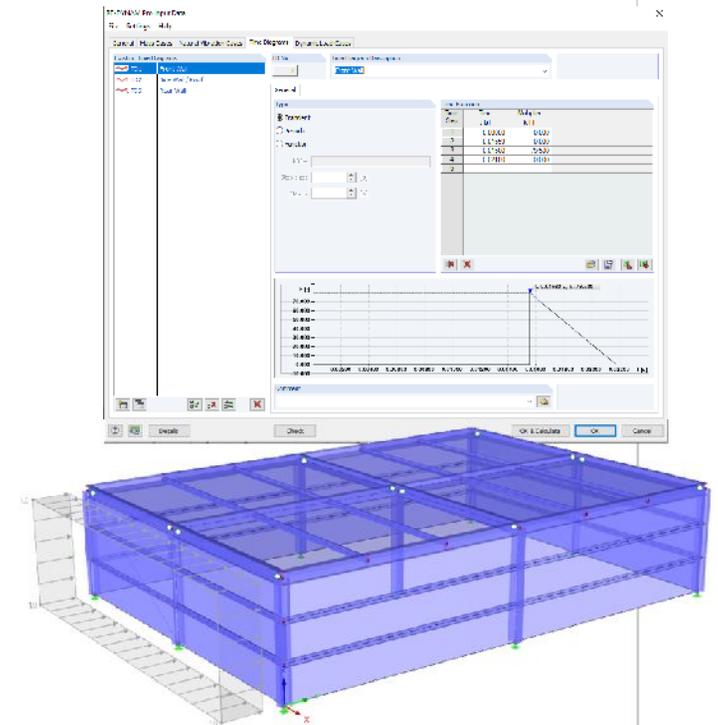

- 01 Blast loading concept
- 02 Blast time history example in RFEM
- 03 Natural vibration analysis utilizing RF-DYNAM PRO – Natural Vibrations
- 04 Linear time history analysis utilizing RF-DYNAM PRO – Forced Vibrations
- 05 Nonlinear time history analysis with RF-DYNAM PRO – Nonlinear Time History
- 06 Structure response and results evaluation

Blast Loading Basics

- **Design Resources**
 - AISC Design Guide 26 – Design of Blast Resistant Structures (AISC, 2013)
 - United Facilities Criteria 3-340-02, Structures to Resist the Effects of Accidental Explosions (DOD, 2008)
- **Factors influencing structural damage**
 - Structure materials, mass, stiffness
 - Explosive type and distance to structure
 - Blast orientation to structure and surrounding structures
- **Design Goals**
 - Avoid loss of life not necessarily avoid extensive structural damage
 - Steel often used as primary structural system for blast due to large inelastic deformation capability without loss of load carrying ability
 - Concrete has a higher mass and stiffness with higher temperature resistance

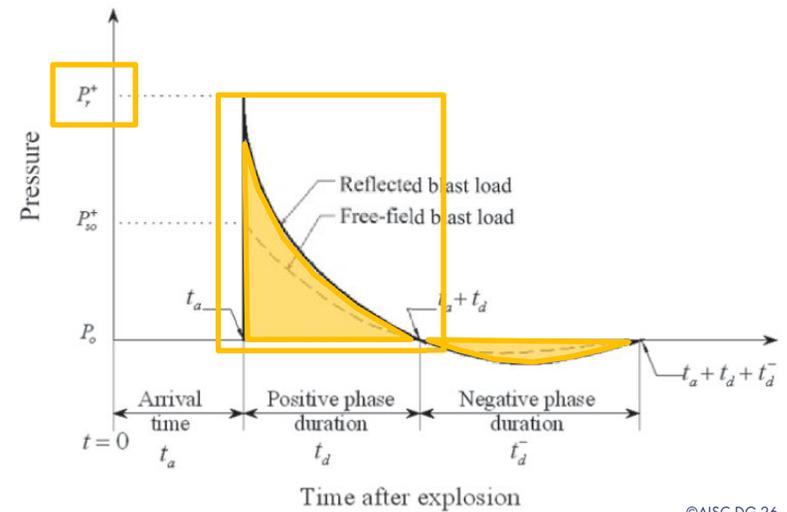

Blast Load Application

Idealized pressure-time history for blast load

- Peak overpressure (pressure above ambient atmospheric pressure) is an instantaneous pressure arriving at structure
- Positive phase duration is time period for pressure to return to ambient
- Positive impulse is total pressure-time energy applied during positive duration (area under curve)
- Negative phase duration, energy, impulse follows positive phase (pressure falls below atmospheric pressure)

©AISC DG 26

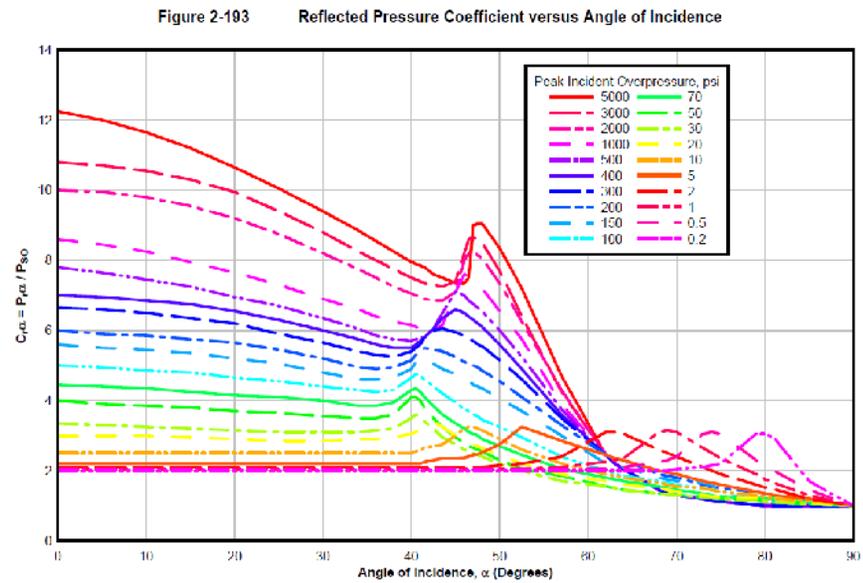

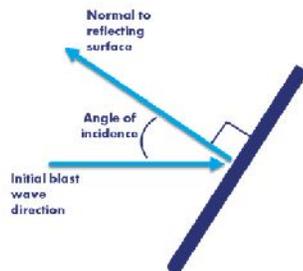

Blast Load Application (cont'd)

- **Free-field (side-on) blast load**
 - Blast load travels parallel to a surface
 - Sweep over the surface with no impeding objects
 - Subscript "so" used for side-on
- **Reflected blast load**
 - Blast load strikes an angled surface other than parallel

$$P_r = C_r P_{so}$$

©UFC 3-340-02

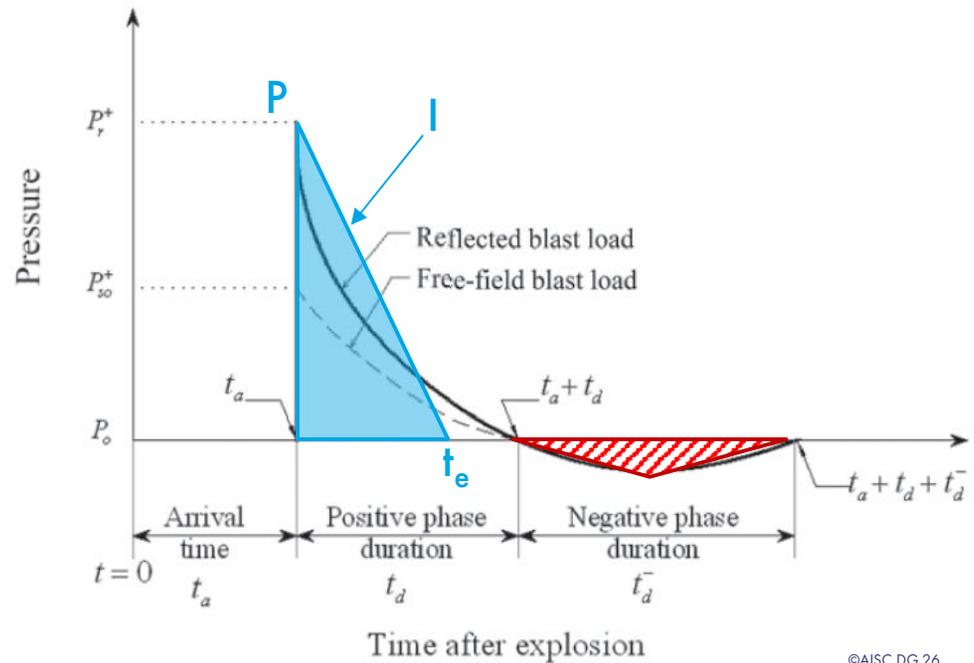

Blast Load Simplification

- **Pressure-time history positive phase**

 - Simplified to a triangular distribution w/ instantaneous rise and linear decay
 - Peak pressure and impulse are preserved
 - Fictious duration, $t_e = 2(I/P)$
- **Pressure-time history negative phase**

 - Neglected for this demonstration
 - Considered when elements are weaker in the reverse loading direction or for short natural periods compared to the load duration
- **Other considerations**

 - Drag forces due to wind (dynamic) pressures
 - Large openings to account for interior loads due to leakage
 - Shielding (load reduction) and reflection (load amplification)

- Nonlinear Time History

— AISC DG 26 – Example 2.1

Given:

- One-story steel building ; 50 ft x 70 ft x 15 ft
- Short direction – braced frames ; long direction – rigid frames
- Hot rolled sections ; ribbed metal panels
- Blast $W = 500 \text{ lb}$; $R = 50 \text{ ft}$ from structure

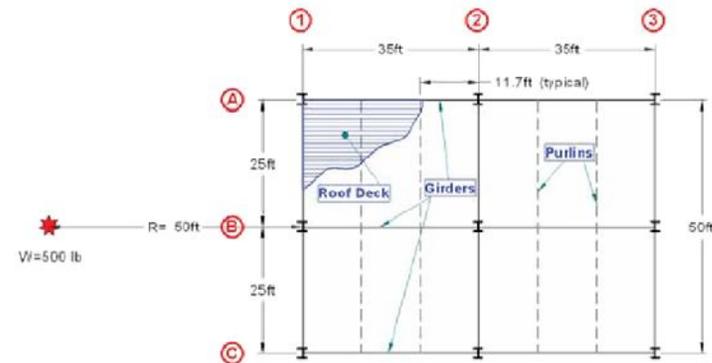

Fig. 2-9. Steel building—plan view.

Fig. 2-10. Steel building—elevation.

©AISC DG 26

AISC DG 26 – Example 2.1 (cont'd)

Solution:

- Scaled distance

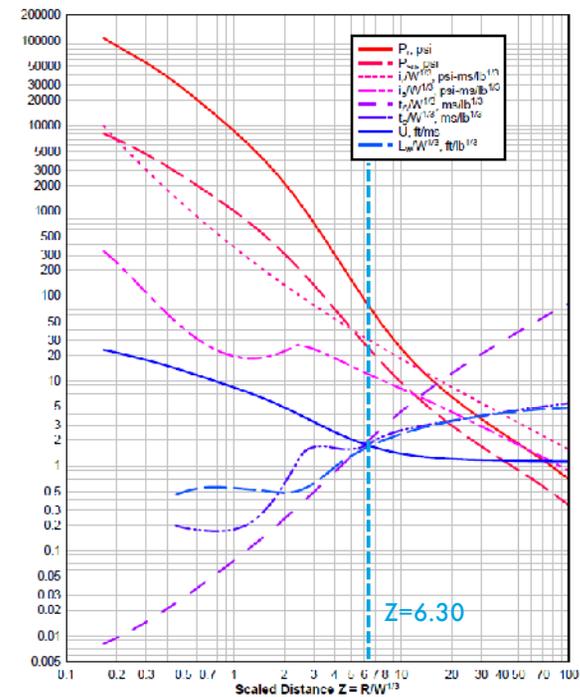

$$Z = \frac{R}{\sqrt[3]{W}} = \frac{50 \text{ ft}}{\sqrt[3]{500 \text{ lb}}} = 6.3 \frac{\text{ft}}{\text{lb}^{1/3}}$$

- Parameters for blast loading (UFC 3-340-02)

Blast Loading Parameters	From Figure 2-15	Calculated
Reflected peak pressure (+)	$P_r = 79.5 \text{ psi}$	—
Side-on peak pressure (+)	$P_{so} = 24.9 \text{ psi}$	—
Reflected impulse (+)	$I_r = 31.0W^{1/3}$	$I_r = 246 \text{ psi ms}$
Side-on impulse (+)	$I_{so} = 12.1W^{1/3}$	$I_{so} = 96.0 \text{ psi ms}$
Time of arrival	$t_a = 1.96W^{1/3}$	$t_a = 15.6 \text{ ms}$
Exponential load duration (+)	$t_d = 1.77W^{1/3}$	$t_d = 14.0 \text{ ms}$
Shock front velocity	$U = 1.75 \text{ ft/ms}$	—

Figure 2-15 Positive Phase Shock Wave Parameters for a Hemispherical TNT Explosion on the Surface at Sea Level

©UFC 3-340-02

AISC DG 26 – Example 2.1 (cont'd)

Reflected pressure (front wall):

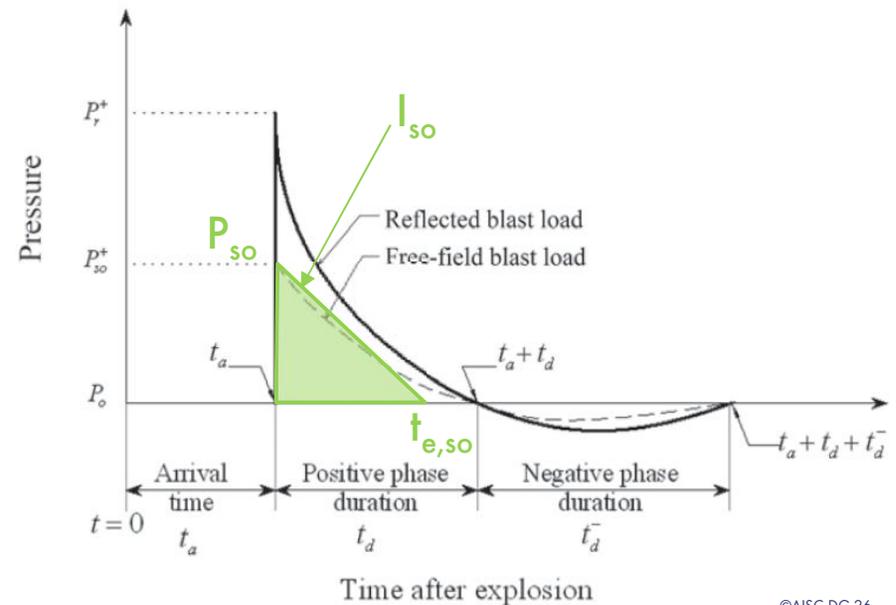

- Equivalent triangular shape with peak pressure (P_r) and impulse (I_r) values are preserved
- Equivalent duration for positive phase blast load for reflected pressure

$$t_{e,r} = \frac{2I_r}{P_r} = \frac{2(246 \text{ psi ms})}{29.5 \text{ psi}} = 6.19 \text{ ms}$$

Side-on pressure (side wall and roof):

- Simplicity, use scaled distance, Z = front wall centerline for side walls and roof
- Equivalent duration for positive phase blast load for side-on pressure

$$t_{e,so} = \frac{2I_{so}}{P_{so}} = \frac{2(96.0 \text{ psi ms})}{24.9 \text{ psi}} = 7.71 \text{ ms}$$

©AISC DG 26

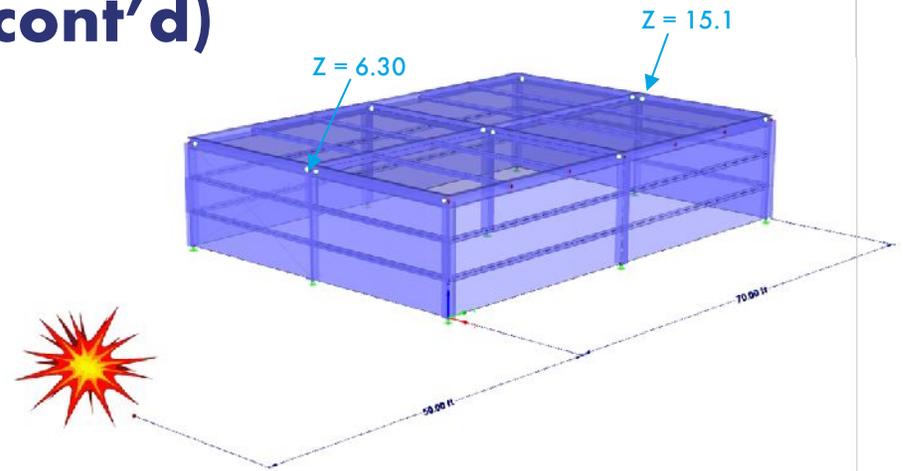

AISC DG 26 – Example 2.1 (cont'd)

Rear Wall

- Charge distance, $R = 50 \text{ ft} + 70 \text{ ft} = 120 \text{ ft}$
- Scaled distance, $Z = \frac{R}{\sqrt[3]{W}} = \frac{120 \text{ ft}}{\sqrt[3]{500 \text{ lb}}} = 15.1 \frac{\text{ft}}{\text{lb}^{1/3}}$
- Parameters for blast loading (UFC 3-340-02)
- Equivalent duration for positive phase blast load for side-on pressure

$$t_{e,so} = \frac{2I_{so}}{P_{so}} = \frac{2(44.0 \text{ psi ms})}{4.60 \text{ psi}} = 19.1 \text{ ms}$$

Blast Loading Parameters	From Figure 2-15	Calculated
Side-on peak pressure (+)	$P_{so} = 4.60 \text{ psi}$	—
Side-on impulse (+)	$I_{so} = 5.54W^{1/3}$	$I_{so} = 44.0 \text{ psi ms}$
Time of arrival	$t_a = 8.32W^{1/3}$	$t_a = 66.0 \text{ ms}$
Exponential load duration (+)	$t_d = 3.11W^{1/3}$	$t_d = 24.7 \text{ ms}$
Shock front velocity	$U = 1.26 \text{ ft/ms}$	—

AISC DG 26 – Example 2.1 (cont'd)

Rear Wall (cont'd)

- Time of arrival, $t_a = 66.0$ ms
- Time to peak pressure, t_2

$$t_2 = \frac{L_1}{U} + t_a = \frac{15.0 \text{ ft}}{1.26 \text{ ft/ms}} + 66.0 \text{ ms} = 77.9 \text{ ms}$$

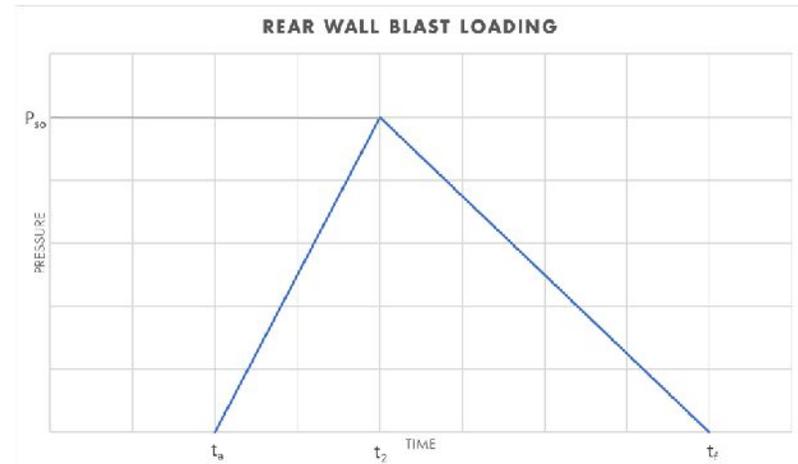

Where,

L_1 = span of element parallel to traveling wave
= building height (15 ft)

U = shock front velocity (UFC 3-340-02 Figure 2-15)

- Time to end of blast load (+), t_f

$$t_f = t_2 + t_{e,s0} = 77.9 \text{ ms} + 19.1 \text{ ms} = 97.0 \text{ ms}$$

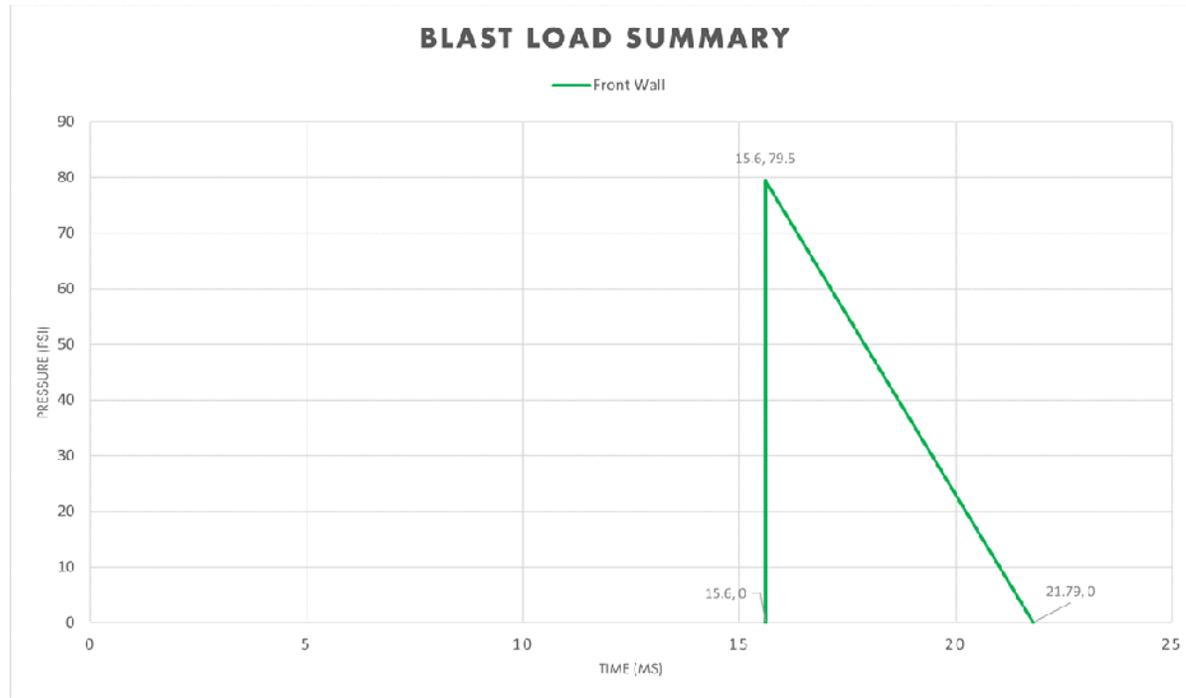

AISC DG 26 – Example 2.1 (cont'd)

Blast Load Summary

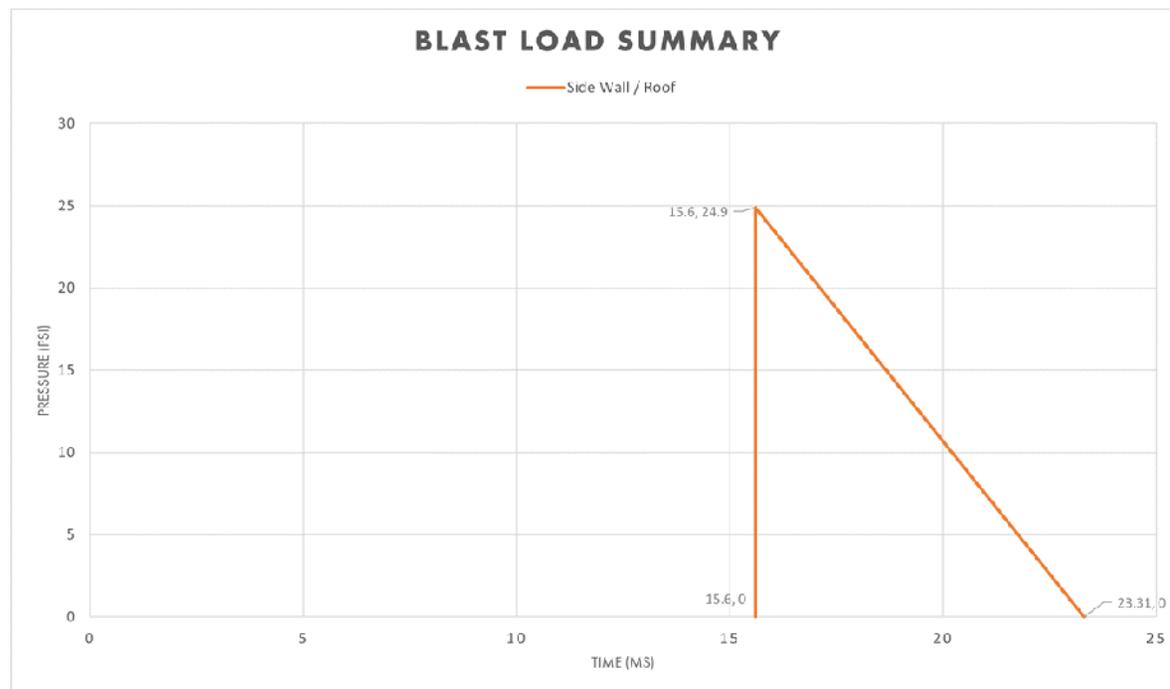

- Plot showing pressure vs. time of blast wave for front, side/roof, and rear walls
- Equivalent triangular loading function used over more exact loading function
- Negative phase of shock and other variables (dynamic pressure, openings, etc.) not included
- For simplicity, full side-on pressures computed for nonreflected surfaces (side walls, roof, rear wall) rather than load averaging techniques in UFC 3-340-02
